Evidence for the involvement of heme-independent
```

radicals in fluorine-induced liver injury. In experiments where Fischer rats were fluorosed and then exposed to X-rays, their ability to repair oxygen-dependent radicals was significantly impaired when liver lesions were observed. When the same animals received fluorosis and were protected from free radical damage by large doses of riboflavin the ability to repair oxygen radicals was restored to control levels. Thus, in the presence of liver damage, fluorides seem to act in a manner similar to that of free radicals. It is suggested that heme-independent free radicals produced by the attack of fluorides on serum albumin may be involved in liver lesions. Novel candidate gene for seed protein content in maize. Several genes that regulate the accumulation of seed storage proteins in maize have been cloned and their functions elucidated. However, most of these studies have focused on genes that control

the accumulation of storage proteins in the endosperm of the developing grain. In this study, DNA-DNA and DNA-cDNA hybridization, in situ hybridization, and RFLP-based mapping techniques were used to investigate the presence of a gene that may influence the accumulation of endosperm proteins in developing grain, a putative novel regulatory gene that is expressed prior to cellularisation of the endosperm in maize. The sequences of two DNA fragments from the maize haploid, Mo17B, which have been previously identified as associated with
